

Comprehensive Guide to Chemical Compounds, Bonding, and Reactions

Ionic and Network Covalent Compounds

Ionic compounds and network covalent compounds are characterized by fixed ratios of elements, known as **empirical formulas**, but they can contain a variable number of atoms per particle, called **formula units**. Examples include:

- **Sodium chloride (NaCl):** An ionic compound formed by electrostatic attraction between Na^+ and Cl^- ions.
- **Silicon dioxide (SiO_2):** A network covalent compound where each silicon atom is covalently bonded to four oxygen atoms in a continuous three-dimensional network.

Key points:

- Ionic compounds typically form crystalline solids with high melting points.
- Network covalent compounds also have high melting points due to strong covalent bonds throughout the structure.
- The fixed ratio indicates a specific chemical formula, but the structure can extend infinitely in a network or lattice.

VSEPR Theory and Molecular Geometry

The **Valence Shell Electron Pair Repulsion (VSEPR)** theory predicts the three-dimensional shapes and bond angles of molecules by considering the repulsion between electron pairs (bonding and lone pairs) around a central atom.
