## Packet Switching:

To send a message from a source end system to a destination end system, the source breaks long messages into smaller chunks of data known as **packets**. Between source and destination, each packet travels through **communication links** and **packet switches** (routers and link-layer switches).

Packets are transmitted over each communication link at a rate equal to the full transmission rate of the link. So, if a source end system or a packet switch is sending a packet of  $L$  bits over a link with transmission rate  $R$  bits/sec, then the time to transmit the packet is  $L/R$  seconds, where packet contains  $L$  bits.

## Store-and-Forward Transmission

Store-and-forward transmission means that the packet switch must receive the entire packet before it can begin to transmit the first bit of the packet onto the **outbound link**.

### For Example:

The source has three packets, each consisting of  $L$  bits, to send to the destination. The source has

Figure 1.11 • Store-and-forward packet switching

transmitted some of packet 1, and the front of packet 1 has already arrived at the router. Because the router employs **store-and-forwarding**, at this instant of time, the router cannot transmit the bits it has received; instead it must first buffer (i.e., “store”) the packet’s bits. Only after the router has received all of the packet’s bits can it begin to transmit (i.e., “forward”) the packet onto the outbound link.

Suppose propagation time is negligible, the source begins to transmit at time 0; at time  $L/R$  seconds, the source has transmitted the entire packet, and the entire packet has been received and stored at the router (since there is no propagation delay). At time  $L/R$  seconds, since the router has just received the entire packet, it can begin to transmit the packet onto the outbound link towards the destination; at time  $2L/R$ , the router has transmitted the entire packet, and the entire packet has been received by the destination. **Thus, the total delay is  $2L/R$ .**

**Note:** If the switch instead forwarded bits as soon as they arrive (without first receiving the entire packet), then the total delay would be  $L/R$  since bits are not held up at the router.

At time  $L/R$ , the router begins to forward the first packet. But also at time  $L/R$  the source will begin to send the second packet, since it has just finished sending the entire first packet. Thus, at time  $2L/R$ , the destination has received the first packet and the router has received the second packet. **Finally, at time  $4L/R$  the destination has received all three packets!**
