

Chapter 10: Nuclear Reactions

Goals of Period 10

Section 10.1: To describe the half-life of nuclei and radio-carbon dating

Section 10.2: To further explore the relationship between mass and energy

Section 10.3: To calculate the binding energy of atomic nuclei

In Period 8 we discovered that unstable isotopes tend to decay into more stable nuclei. In Period 9 we found that unstable isotopes can decay by emitting alpha, beta, or gamma radiation, or by nuclear fission. Next we discuss the rate at which an isotope decays – the half life of the isotope. We then examine the effect on the mass and the energy of a nucleus when ionizing radiation is emitted.

10.1 Rates of Radioactive Decay

Half-Life

The decay of unstable, radioactive nuclei is a random process, and it is impossible to predict when a given nucleus will decay. Nuclei do not all decay at once, nor do those that have lived a long time show signs of aging like people do. The best one can do is to make the statistical statement that half the nuclei in a large sample of an unstable isotope will decay in a time characteristic of that isotope, called the **half-life** of the isotope and denoted by $T_{1/2}$. A similar statistical statement would be that in a large sample of coin tosses, half would come up heads. However, this does not mean that you get 5 heads in every 10 tosses nor does it tell you which of the coins will come up heads and which will come up tails.

In Period 1 we discussed exponential growth and decay. In exponential growth, a quantity doubles its size in a characteristic time called the doubling time. The equation describing exponential growth is

$$N = B \times 2^t \quad \text{(Equation 10.1)}$$

where

N = the amount of the quantity at a given time

t = the number of time periods elapsed

B = the initial amount of the quantity

In exponential decay, a quantity decreases by one half in a characteristic time, called the half life. A radioactive isotope is described by exponential decay, in which (statistically) the number of nuclei of the isotope is cut in half in a characteristic time, $T_{1/2}$. The equation for exponential decay is

$$N = B \times 2^{-t} = B \times \frac{1}{2^t} \quad \text{(Equation 10.2)}$$

Table 10.1 uses this relationship to compare the number of half lives elapsed to the portion of a sample remaining.
