Program scheduling and simulation in an operating system environment bernard lampard, 2014-02-03 Research Paper postgraduate from the year 2011 in the subject Computer Science Commercial Information Technology grade A Massachusetts Institute of Technology language English abstract CPU scheduling is a

technique used by computer operating systems to manage the usage of the computer's central processing unit. In a multi-programming environment whereby several processes are running on the same processor, it is essential to use scheduling criteria to avoid collisions in the computer's operations. This will help users in a given information technology-oriented firm to share server spaces and resources like printers and file storage spaces. In the multi-tasking environment, a program called CPU scheduler selects one of the ready processes and allocates the processor to it. There are a number of occasions when a new process can or must be chosen to run. When a running process blocks and changes its state to Blocked. When a timer for a running process expires. When a waiting process unblocks and changes its state to Ready. And when a running process terminates and changes its state to Exit. Wikipedia 2013. Different types of scheduling programs referred to as algorithms can be employed in CPU scheduling instances. Among the most popular scheduling algorithms is Shortest Job First (SJF). SJF gives the processor to the process with the shortest next time allocation, known as the burst. If there are processes with similar CPU bursts in the event queue, the scheduler uses First Come First Served algorithm, which allocates the first process to arrive in the queue to the processor regardless of its burst time. It operates under the assumption that the length of the next CPU burst of each of the processes in the ready queue is known. CPU scheduling 2013. The SJF algorithm can be used in both pre-emptive and non-pre-emptive methods. The algorithm can be pre-emptive or not. Shortest Job First with pre-emption uses priority measure to determine the next process to be given the CPU. The processes will be having different CPU bursts and different priority levels allocated to them. The process with the least priority magnitude is always picked next. A process already allocated the processor can be pre-empted the CPU and allocation done to another process with higher priority when such a process arrives in the queue. SJF with non-pre-emptive operates in the normal procedure whereby the job with the least CPU burst in the waiting queue is always picked next for allocation of the CPU and the rest of the processes have to wait no matter their urgency. Based on the introduction above, it is essential to use the right CPU scheduling strategy to help us achieve.
