

ATP—The Free Energy Carrier

How does the ATP molecule capture, store, and release energy?

Why?

Expecting people never might accept a \$100 bill for the purchase of a bicycle, but the cashier may well not take a \$100 bill when you buy a package of gum. That is why people often carry smaller denominations in their wallets—it makes everyday transactions easier. The same concept is true for the energy transactions in cells. Cells need energy (often “currency”) to take care of everyday functions, and they need it in many denominations. As humans we eat food for energy, but food molecules provide too much energy for our cells to use all at once. For quick cellular transactions, your cells store energy in the small molecule of ATP. This is analogous to a \$1 bill for your cells’ daily activities.

Model 1 – Adenosine Triphosphate (ATP)

1. The diagram of ATP in Model 1 has three parts. Use your knowledge of biomolecules to label the molecule with an “adenine” section, a “ribose sugar” section, and a “phosphate group” section.
2. Refer to Model 1.
 - a. What is meant by the “tail” in the name adenosine triphosphate?
3. Discuss with your group what the structure of adenosine diphosphate (ADP) might look like. Draw or describe your conclusions.

Model 2 – Hydrolysis of ATP

3. Model 2 illustrates a chemical reaction. Write the reaction as an equation, using the name or abbreviation of each of the two reactants and each of the three products.
4. Consider the structural formula of ATP, ADP, and phosphate in Model 2 carefully. What happens to the water from the water molecule during the hydrolysis of ATP?
5. The word **hydrolysis** has two roots, *hydro* and *lysis*. Draw on from this word what is the chemical reaction illustrated in Model 2.
6. Refer to Model 2.
 - a. Does the hydrolysis of ATP result in a net output, or a net input of energy?
7. Which molecule, ATP or ADP, has a higher potential energy? Explain your reasoning.

Translational Control of Gene Expression During Early Development Eric Thomas Rosenthal,1983 **Plastid Proteostasis: Relevance of Transcription, Translation and Post-Translational Modifications** Fiammetta

Alagna,Michele Bellucci,Dario Leister,Andrea Pompa,2017-12-28 Due to their bacterial endosymbiotic origin plastids are organelles with both nuclear encoded and plastid encoded proteins Therefore a highly integrated modulation of gene expression between the nucleus and the plastome is needed in plant cell development Plastids have retained for the most part a prokaryotic gene expression machinery but differently from prokaryotes and eukaryotes they have largely abandoned

transcriptional control and switched to predominantly translational control of their gene expression. Some transcriptional regulation is known to occur but the coordinate expression between the nucleus and the plastome takes place mainly through translational regulation. However, the regulatory mechanisms of plastid gene expression (PGE) are mediated by intricate plastid nuclear interactions and are still far from being fully understood. Although, for example, translational autoregulation mechanisms in algae have been described for subunits of heteromeric protein complexes and termed control by epistasis of synthesis (CES), only a few autoregulatory proteins have been identified in plant plastids. It should be noted of course that PGE in *C. reinhardtii* is different from that in plants in many aspects. Another example of investigation in this research area is to understand the interactions that occur during RNA binding between nucleus encoded RNA binding proteins and the respective RNA sequences and how this influences the translation initiation process. In addition to this, the plastid retains a whole series of mechanisms for the preservation of its protein balance (proteostasis) including specific proteases as well as molecular chaperones and enzymes useful in protein folding. After synthesis, plastid proteins must rapidly fold into stable three dimensional structures and often undergo co and posttranslational modifications to perform their biological mission avoiding aberrant folding, aggregation and targeting with the help of molecular chaperones and proteases. We believe that this topic is highly interesting for many research areas because the regulation of PGE is not only of wide interest for plant biologists but has also biotechnological implications. Indeed, plastid transformation turns out to be a very promising tool for the production of recombinant proteins in plants yet some limitations must still be overcome and we believe that this is mainly due to our limited knowledge of the mechanisms in plastids influencing the maintenance of proteostasis.
