Muehlbauer, 2009-06-10 Sequencing of the model plant genomes such as those of *A. thaliana* and rice has revolutionized our understanding of plant biology but it has yet

to translate into the improvement of major crop species such as maize wheat or barley Moreover the comparative genomic studies in cereals that have been performed in the past decade have revealed the limits of conservation between rice and the other cereal genomes This has necessitated the development of genomic resources and programs for maize sorghum wheat and barley to serve as the foundation for future genome sequencing and the acceleration of genomic based improvement of these critically important crops Cereals constitute over 50% of total crop production worldwide [http www fao org](http://www.fao.org) and cereal seeds are one of the most important renewable resources for food feed and industrial raw materials Crop species of the Triticeae tribe that comprise wheat barley and rye are essential components of human and domestic animal nutrition With 17% of all crop area wheat is the staple food for 40% of the world s population while barley ranks fifth in the world production Their domestication in the Fertile Crescent 10 000 years ago ushered in the beginning of agriculture and signified an important breakthrough in the advancement of civilization Rye is second after wheat among grains most commonly used in the production of bread and is also very important for mixed animal feeds It can be cultivated in poor soils and climates that are generally not suitable for other cereals Extensive genetics and cytogenetics studies performed in the Triticeae species over the last 50 years have led to the characterization of their chromosomal composition and origins and have supported intensive work to create new genetic resources Cytogenetic studies in wheat have allowed the identification and characterization of the different homoeologous genomes and have demonstrated the utility of studying wheat genome evolution as a model for the analysis of polyploidization a major force in the evolution of the eukaryotic genomes Barley with its diploid genome shows high collinearity with the other Triticeae genomes and therefore serves as a good template for supporting genomic analyses in the wheat and rye genomes The knowledge gained from genetic studies in the Triticeae has also been used to produce Triticale the first human made hybrid crop that results from a cross between wheat and rye and combines the nutrition quality and productivity of wheat with the ruggedness of rye Despite the economic importance of the Triticeae species and the need for accelerated crop improvement based on genomics studies the size 1.7 Gb for the bread wheat genome i e 5x the human genome and 40 times the rice genome high repeat content 80% and complexity polyploidy in wheat of their genomes often have been considered too challenging for efficient molecular analysis and genetic improvement in these species Consequently Triticeae genomics has lagged behind the genomic advances of other cereal crops for many years Recently however the situation has changed dramatically and robust genomic programs can be established in the Triticeae as a result of the convergence of several technology developments that have led to new more efficient scientific capabilities and resources such as whole genome and chromosome specific BAC libraries extensive EST collections transformation systems wild germplasm and mutant collections as well as DNA chips Currently the Triticeae genomics toolbox is comprised of 9 publicly available BAC libraries from diploid 5 tetraploid 1 and hexaploid 3 wheat 3 publicly available BAC libraries from barley and one BAC library from rye 3 wheat chromosome specific BAC libraries DNA chips

including commercially available first generation chips from AFFYMETRIX containing 55 000 wheat and 22 000 barley genes. A large number of wheat and barley genetic maps that are saturated by a significant number of markers. The largest plant EST collection with 870 000 wheat ESTs, 440 000 barley ESTs and about 10 000 rye ESTs. Established protocols for stable transformation by biolistic and agrobacterium as well as a transient expression system using VIGS in wheat and barley and large collections of well characterized cultivated and wild genetic resources. International consortia such as the International Triticeae Mapping Initiative ITMI have advanced synergies in the Triticeae genetics community in the development of additional mapping populations and markers that have led to a dramatic improvement in the resolution of the genetic maps and the amount of molecular markers in the three species resulting in the accelerated utilization of molecular markers in selection programs. Together with the development of the genomic resources the isolation of the first genes of agronomic interest by map based cloning has been enabled and has proven the feasibility of forging the link between genotype and phenotype in the Triticeae species. Moreover the first analyses of BAC sequences from wheat and barley have allowed preliminary characterizations of their genome organization and composition as well as the first inter and intra specific comparative genomic studies. These later have revealed important evolutionary mechanisms e.g. unequal crossing over illegitimate recombination that have shaped the wheat and barley genomes during their evolution. These breakthroughs have demonstrated the feasibility of developing efficient genomic studies in the Triticeae and have led to the recent establishment of the International Wheat Genome Sequencing Consortium IWGSC (<http://www.wheatgenome.org>) and the International Barley Sequencing Consortium (www.isbc.org) that aim to sequence respectively the hexaploid wheat and barley genomes to accelerate gene discovery and crop improvement in the next decade. Large projects aiming at the establishment of the physical maps as well as a better characterization of their composition and organization through large scale random sequencing projects have been initiated already. Concurrently a number of projects have been launched to develop high throughput functional genomics in wheat and barley. Transcriptomics, proteomics and metabolomics analyses of traits of agronomic importance such as quality, disease resistance, drought and salt tolerance are underway in both species. Combined with the development of physical maps, efficient gene isolation will be enabled and improved sequencing technologies and reduced sequencing costs will permit ultimately genome sequencing and access to the entire wheat and barley gene regulatory elements repertoire. Because rye is closely related to wheat and barley in Triticeae evolution the latest developments in wheat and barley genomics will be of great use for developing rye genomics and for providing tools for rye improvement. Finally a new model for temperate grasses has emerged in the past year with the development of the genetics and genomics including a 8x whole genome shotgun sequencing project of *Brachypodium*, a member of the Poaceae family that is more closely related to the Triticeae than rice and can provide valuable information for supporting Triticeae genomics in the near future. These recent breakthroughs have yet to be reviewed in a single source of literature and current handbooks.

on wheat barley or rye are dedicated mainly to progress in genetics In Genetics and Genomics of the Triticeae we will aim to comprehensively review the recent progress in the development of structural and functional genomics tools in the Triticeae species and review the understanding of wheat barley and rye biology that has resulted from these new resources as well as to illuminate how this new found knowledge can be applied for the improvement of these essential species The book will be the seventh volume in the ambitious series of books Plant Genetics and Genomics Richard A Jorgensen series editor that will attempt to bring the field up to date on the genetics and genomics of important crop plants and genetic models It is our hope that the publication will be a useful and timely tool for researchers and students alike working with the Triticeae

There have been many advances in clinical cytogenetics since the first edition of this book appeared in 1989 The authors have written more expansively on segregation and risks in reciprocal translocations X autosome translocations inversions insertions and prenatal diagnosis The deletion syndromes have become more numerous and more precisely defined and this required treatment Fluorescence in situ hybridization has become a routinely applied methodology and its use has extended the power and increased the sophistication of the discipline of clinical cytogenetics The Human Genome Project is unravelling the complexity of our

genetic inheritance and readers will find evidence of its impact on the practicalities of human cytogenetics throughout the book Two phrases not used at all in the first edition are dynamic mutation and genomic imprinting The fragile X syndrome now has the status of the prototypical dynamic mutation The authors completely rewrote this chapter giving it a much more molecular character The Prader Willi and Angelman syndromes likewise have become the classic examples of genomic imprinting and uniparental disomy Compared with the tentative comments on these syndromes in the first edition they now receive more extensive treatment Yet while the subject has become more complicated the book s aim remains the same to furnish a straightforward scientific description that will help readers understand the various chromosome abnormalities encountered in clinical practice and to provide practical advice that can be passed on to the people who have or whose families have these abnormalities
