ABSTRACT

The odontogenic myxoma (OM) is a locally invasive benign odontogenic tumour of the jaws, thought to originate from the mesenchymal portion of the tooth germ. It commonly manifests in individuals during their second or third decade of life.

Females experience a higher frequency of occurrences compared to males, and there is a greater inclination for odontogenic myxoma to affect the mandible rather than the maxilla. In most cases, OM manifests as an asymptomatic swelling. Due to its non-capsulated and aggressive nature, there is a notable high recurrence rate reported.

Small myxomas are typically addressed through curettage, but it is crucial to conduct thorough follow-up examinations for a minimum of 5 years. The standard treatment for myxoma typically involves surgical resection.

Our article highlights two instances of odontogenic myxoma occurring in separate locations. The emphasis is on summarizing distinctive clinical and radiological behaviour of these lesions manifesting in the maxilla and mandible.

1. Introduction

The odontogenic myxoma (OM), a benign non-encapsulated odontogenic tumor, was first described by Thomas and Goldman in 1947.¹ German pathologist Rudolph Virchow coined the term "myxoma" in 1871 to characterise tumors that shared similar histological characteristics with the mucinous tissue of the umbilical cord.¹

According to the 2022 World Health Organization Classification of Odontogenic Lesions, OM comes under benign mesenchymal odontogenic tumor.² It is a rare tumor, with or without the presence of odontogenic epithelium, and is referred to as "locally malignant" due to its remarkably high local aggressiveness and non-metastasizing nature.^{3,4} with a low prevalence of 3-6% of odontogenic tumor.^{1,5}

Radiographically, OM appears as a well-defined unilocular or multilocular osteolytic lesion with the appearance of a "soap bubble".^{5,6} The distinguishing feature associated with this tumor is the presence of a straight, thin, finely detailed septum. While these septa have been likened to a tennis racket or stepladder pattern, such configurations are infrequently observed. In reality, the majority of septa exhibit a curved and coarse structure. However, the identification of one or two of these straight septa significantly aids in recognizing this tumor.⁷

2. Case Report**2.1. Case 1**

A 40-year-old male reported to our department with pain and swelling on the right mandible, following a bike fall a year ago. Initial trauma led to a pea-sized swelling,
