Autocar, 2005 **Study Characteristic of Engine Mount for Effectively Reducing the Vibration of Car Engine**

Tushar Uttamrao Patil, 2014 Comfortable ride is one of the main index of comfortable vehicle and engine mount plays important role in it. Automobile industries are in need of reducing the vibration forces to satisfy customer requirements. Vibration of car engine arises from unbalanced forces of engine which are transmitted from engine to chassis and road induced vibration which is controlled by using proper engine mounts and suspension system. The purpose of this thesis is to study the vibration of automobile engine. Engine mount with elastomeric and hydraulic mounts are developed. Their performance is evaluated using bond graph on entire frequency range. Engine mount parameters are optimized by using bond graph optimization method. Sources of engine excitation forces are identified. Engine reciprocating and rotating parts contribute in generating vertical excitation forces. Mounts characteristics are analyzed by their excitation frequency and amplitude. Hydraulic engine mounts are more effective than rubber mounts because their frequency and amplitude response is superior. Fluid analysis is more complex so linear models and theory on two degree of freedom is developed in this thesis. Presently, companies are more concerned about customer satisfaction in automobile industries. Passengers may get more comfort if vibration induced due to uneven road or engine is reduced. Selection of proper engine mount location and optimization of mounts parameter as per application is required. Force transmitted to passengers needs to be reduced. In this thesis, I applied knowledge from my curricular courses like vibration technology and computer aided design of dynamic system which helped me to build bond and block diagram of whole powertrain system. I used software CAMPG, Matlab, Mathematica and Nastran to optimize parameter. Hydraulic engine mounts can be made more effective by varying the inertia area and stiffness parameter. They can operate on wide frequency range by varying stiffness using inertia area. Transmissibility is reduced which enables more comfortable ride.

Modeling and Control of Active Engine Mounts Ahmed Murgab Mohammed Mahil, 2014 The automobile industry has developed significantly through years and producing fuel efficient cars became the most important priority for automobile manufacturers and that will affect the cars weight to make them lighter using composites and alloys that is lighter than steel and have a better strength to weight ratio and therefore have a low fuel consumption and by utilizing efficient engine mounts powerful engines can be installed into light vehicles yet such mounts are seldom and the introduction of more powerful engines to lighter cars will cause more vibrations that will not likely be damped by the traditional mounts specifically the low frequency vibrations and that will affect the passengers comfort and health. In order to remedy this quagmire active engine mounts were introduced. The typical active engine mount consists of a rubber passive mount and a force actuator that will be activated at certain frequencies and generate a damping force approximately equal to the disturbance force. Thus these systems will reduce the amount of vibrations that reaches the passenger cabin more than the passive and semi active engine mount systems. Many control techniques have been investigated in order to enhance the

performance of the active mounting yet most of the control techniques has been implemented on unrealistic models and it is seldom to find any realistic model of active engine mount. In this dissertation classical and modern controllers have been introduced on three different models starting from two degree of freedom unrealistic model and then a moderately realistic four degree of freedom model and finally a realistic six degree of freedom model. Two control techniques were implemented on the different systems namely PID proportional integral derivative LQR linear quadratic regulator respectively. Then comparison was done between their simulation results and performance assessment for the controllers. Simulation results were conducted and showed a significant enhancement in isolating the vibrations of the engine from the car body.

Analytical Investigation of the Dynamic Properties of Passive Engine Mounting Fazidah binti Saad, 2011. Engine mount is an automotive component that is essential in supporting the engine static state in order to prevent engine bounce from shock excitation and to isolate engine vibration caused by engine disturbances in the complete speed range. The main objective of this study is to analyze the dynamic properties which are the natural frequencies and modeshapes of different types of passive engine mounts. In this study four passive rubber engine mount models were considered. The modal analysis was computed by using finite element software ABAQUS and the results obtained were the modeshapes of the engine mounts. Modeshapes are the deflection shapes taken on by a system when excited at one of its natural frequencies. The corresponding modeshapes of all the rubber engine mount models were computed both in presence and absence of the engine's weight and the results are compared with the results from impact test which has been conducted on one of the engine mounts. The computer simulated model of these mounts was analyzed and later the effect of the load applied on the engine mounts was compared with the engine mounts without the load. The results from the modal analysis demonstrated variety in the natural frequency values for all types of passive engine mounts. The modeshapes results showed the trend of bending mode torsion mode and also the mixture of both. From the modeshapes results the most deformed spot in the engine mounts can be identified. The results showed that the engine mounting with more metal contact will have the highest frequency of 987.56 Hz when analyzed without the engine weight while the engine mount with less metal contact will have the highest frequency of 1456.20 Hz when analyzed with the engine weight. This shows that rubber engine mounts with the least metal contact design had the highest frequency value of all and this signifies that it can provide the best damper for the engine weight. As a conclusion the natural frequency of the passive engine mount depends strongly on the applied load although theoretically the natural frequency of a system should not be affected by the applied load. The variations happen because of the rubber viscoelastic nature. Besides that the natural frequency of the rubber engine mounts also depend on their designs as the least metal contact design showed higher natural frequency value. The results of this study will open up a passage to researchers to study and improve the elastomeric engine mounts.
