

Red blood cells

Red blood cells have a biconcave shape to maximise surface area so the most efficient oxygen absorption. Red blood cells are also flexible to fit through capillaries, which are narrower than arteries and veins. Their main function is to carry oxygen around the body to all respiring tissue and this is why their structure does not consist of any other organelles or nucleus because for maximum oxygen storage. They are produced in the bone marrow and are produced at very quickly (approximately 5000 million per hour). Red bloods cells have a life cycle of 4 months then are broken down in the liver and converted to iron to produce more haemoglobin in which some is excreted.

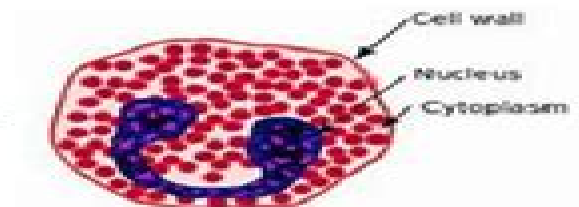

White blood cells

There are many types of white blood cells:

The two most abundant types are phagocytes and lymphocytes. The difference is in the way they deal with foreign microorganisms: phagocytes engulf microorganisms whereas lymphocytes produce antibodies that attack antigens. Typically, lymphocytes make up 25% of white blood cells and phagocytes make up 70% of white blood cells.

Another type of white blood cell are neutrophils, which play an important role in the immune system. This is because the multi lobed within them enables them to squeeze through small gaps when going to the infection site. The cytoplasm of this white blood cell also holds lysosomes that digest pathogens that are ingested by neutrophil.
