communicate to the promoters in a stage specific fashion and in the context of chromatin Because the factors that regulate chromatin are generally present and active in most cell types how could cell type and or stage specific chromatin architecture is achieved in response to a particular immune signal The genetic loci that encode lymphocyte cell surface receptors are in an unrearranged or germline configuration during the early stages of development Thus in addition to expressing lineage and or stage specific transcription factors during each developmental stage lymphocytes also need to rearrange their cognate receptor loci in a strictly ordered fashion Hence there must be a tightly coordinated communication between the recombination machinery and the transcriptional machinery including chromatin regulators at every developmental step Mature B cells also undergo classswitch recombination and somatic hypermutation Importantly along the way these cells must avoid autoimmune responses and only those cells capable of recognizing foreignantigens are preserved to reach peripheral organs where they must function The exquisite regulation that govern chromatin accessibility recombination and transcription regulation in response to the environmental signals in the immune system is discussed here is a series of articles
