

AREA REVIEW: DIABETES MELLITUS

DIABETES MELLITUS: AN OVERVIEW^{1,2}

Stephen L. Pohl, M.D., Linda Gonder-Frederick, M.A., and Daniel J. Cox, Ph.D.
University of Virginia School of Medicine

Diabetes Mellitus is an ancient medical term which early physicians used to designate a mysterious disease characterized by profuse, sweet-tasting urine. As medicine progressed the meaning of the term changed considerably. Unfortunately, the concept that diabetes mellitus is a disease—a distinct pathological entity—has persisted and has caused much confusion both among the general public and within the health care professions. In fact, diabetes is a highly complex phenomenon which defies any simple explanation. It is clear, however, that diabetes is a major health problem which affects up to 5% of the American population and which causes both premature death and major morbidity including blindness, kidney failure, premature cardiovascular disease, and gangrene of the lower extremities. The purpose of this overview is to present a framework for assembling all of the countless facts about diabetes for investigators and practitioners in behavioral medicine. Because of the breadth and complexity of the subject we have had to limit depth of coverage. More detail can be found in the references and in two recently published textbooks (1,2).

DEFINITION AND DIAGNOSIS OF DIABETES

There is a tendency in the medical literature to define diabetes in terms of underlying pathophysiologic processes such as insulin deficiency. We prefer to define diabetes simply as chronic hyperglycemia (high blood glucose concentration). The word chronic is important because hyperglycemia can occur acutely with little or no implication for health. However, to have hyperglycemia for a long period of time usually has a major impact on health. The word hyperglycemia permits a very general point of view regarding what causes diabetes and avoids a number of paradoxes, such as the fact that some people with diabetes actually have elevated levels of insulin in their blood. Furthermore, making the diagnosis of diabetes is virtually always based upon measurement of blood glucose concentration.

Making the diagnosis of diabetes, a seemingly simple task, often presents problems. The reason is that the parameters used

for diagnosis, such as fasting blood glucose level or glucose tolerance test results, are continuously distributed in most populations; that is, there is no cut off level of blood glucose above which one clearly has diabetes or below which one clearly does not have diabetes. In clinical practice it is generally wise to err on the side of under diagnosing diabetes, and most physicians now use a conservative criterion of plasma glucose exceeding 140 mg/dl after an overnight fast on at least two occasions (3). The glucose tolerance test is rarely useful in clinical situations. On the other hand, for research projects which require a definite, if arbitrary, distinction between diabetes and nondiabetes, the glucose tolerance test is the procedure of choice. Standardized methods of procedure and interpretation are available (3).

Classification of Diabetes

Classification of different types of diabetes on the basis of etiology or pathogenesis would be extremely useful for both clinical and research purposes. Unfortunately, such a classification is impossible because of inadequate knowledge regarding the causes of diabetes. For most of this century, the terms juvenile onset and adult onset were used to differentiate the two most common diabetic syndromes. However, classification by age of onset was never satisfactory because juvenile type diabetes can begin late in life and adult type diabetes can begin early in life. In 1979, the National Commission on Diabetes proposed a classification system based on insulin dependence (3), i.e. whether an individual requires insulin in order to survive. Insulin-dependent diabetes (IDDM or Type I) characteristically has its onset before age 30 and affected individuals are usually at or below normal body weight. By definition a person who has IDDM will develop ketoacidosis and die within days to weeks, if not treated with insulin. Non-insulin-dependent diabetes (NIDDM or Type II) characteristically begins after age 40 and 60–90 percent of affected individuals in the U.S. are above normal body weight. Ketoacidosis in NIDDM is rare and generally occurs only following severe physical stress. Non-insulin-dependent diabetes is approximately 20 times more common than insulin-dependent diabetes.

Classification based on insulin dependence is also not entirely satisfactory because many non-insulin dependent diabetics take insulin for its blood glucose lowering effect in hope of delaying or preventing the complications of diabetes. Thus, the majority of people in the United States who take insulin actually have non-insulin-dependent diabetes. Fortunately, the new classification system permits the use of Type I and Type II for IDDM and NIDDM respectively. The new classification system also employs the following terms: gestational diabetes (GDM), for hypergly-

¹ For simplicity and brevity, we use the term "diabetes" throughout this paper. It is important to realize, however, that there are other kinds of diabetes (e.g. diabetes insipidus) and that the proper term is "diabetes mellitus."
