Fowler, 2004 This review focused on the primary literature that described modeled or predicted the probability of postfire mortality in ponderosa pine *Pinus ponderosa* and Douglas fir *Pseudotsuga menziesii* The methods and measurements that were used to predict postfire tree death tended to fall into two general categories those focusing on measuring important aspects of fire behavior the indirect but ultimate cause of mortality and those focusing on tissue damage due to fire the direct effect of fire on plant organs Of the methods reviewed in this paper crown scorch volume was the most effective easiest to use and most popular measurement in predicting postfire mortality in both conifer species In addition to this direct measure of foliage damage several studies showed the importance and utility of adding a measurement of stem bole damage There is no clear method of choice for this but direct assessment of cambium condition near the tree base is widely used in Douglas fir Only two ponderosa pine studies directly measured fine root biomass changes due to fire but they did not use these measurements to predict postfire mortality Indirect measures of fire behavior such as ground char classes may be the most practical choice for measuring root damage This review did not find clear postfire survivability differences between the two species The literature also does not show a consistent use of terminology we propose a standard set of terms and their definitions
